## Factoring Polynomials

A core principle in simplifying rational expressions is factoring polynomials. This involves expressing a polynomial as a product of its irreducible factors. For instance,  $x^2 - 4$  can be factored as  $(x - 2)(x + 2)$ . Mastering factoring techniques dramatically improves the accuracy and efficiency of simplification. Extensive practice with factoring different types of polynomials is crucial for success.

## Common Factors & Cancellation

Once polynomials are factored, identifying and canceling common factors in both the numerator and denominator is essential. This process reduces the expression to its simplest form, akin to canceling common terms in a standard fraction. A step-by-step guide to cancellation helps students visualize the process.

## Domain Considerations

Crucially, simplifying rational expressions requires careful attention to the domain of the variable. Division by zero is undefined, so expressions must be evaluated for any values that would result in a zero in the denominator. This step is often overlooked but is fundamental to ensuring the validity of results.

## Examples and Case Studies

- **Engineering Case Study:** A bridge design project involved modeling the deflection under load. A complex rational expression representing the deflection was derived. Simplifying the expression allowed engineers to easily calculate the deflection at different points and modify the design accordingly, leading to a more robust and efficient bridge structure. This is corroborated by design calculations in structural engineering textbooks.
- **Finance Case Study:** A financial model used to project future stock prices involved a rational expression describing the expected return on investment. Simplifying this expression enabled analysts to isolate the impact of different factors, such as interest rates and market conditions, on the potential returns, enabling quicker and more accurate predictions.

## Simplifying Rational Expressions: Your Ultimate Answer

# Key to Mastery

Navigating the world of algebra can sometimes feel like deciphering a secret code. Among the more intricate concepts are rational expressions. These are essentially fractions where the numerator and denominator are polynomials. While they might look daunting at first glance, with the right approach, simplifying them becomes a manageable and even rewarding skill. This article serves as your comprehensive answer key, demystifying the process of simplifying rational expressions and equipping you with the confidence to tackle them. We'll dive deep into the "how-to," explore common pitfalls, and offer practical tips to make this algebraic journey smoother. So, grab your virtual calculator, a fresh notepad, and let's get started on unlocking the secrets to simplifying rational expressions.

## What Exactly Are Rational Expressions?

Before we get to the simplification part, it's crucial to understand what we're dealing with. A rational expression is defined as a fraction where both the numerator and the denominator are polynomials. A polynomial is an expression consisting of variables and coefficients, that involves only the operations of addition, subtraction, multiplication, and non-negative integer exponents of variables. For example:  $\frac{x+2}{x-3}$  is a rational expression.  $\frac{x^2 - 4}{x+2}$  is another rational expression.  $\frac{5}{x}$  is a rational expression (where the numerator is a constant, a type of polynomial). The key takeaway is that these expressions resemble regular fractions, but with algebraic terms instead of simple numbers. Just like with numerical fractions, rational expressions can often be simplified to their most basic form.

## Why Simplify Rational Expressions?

You might wonder, "Why bother simplifying?" The answer is multifaceted. \* **Clarity and Efficiency:** Just as simplifying  $\frac{4}{8}$  to  $\frac{1}{2}$  makes it easier to understand and work with, simplifying rational expressions makes complex algebraic equations more manageable. It reveals the core relationships between variables. \* **Solving Equations and Inequalities:** Many algebraic problems, including solving equations and inequalities, require rational expressions to be in their simplest form before you can find solutions. \* **Understanding Function Behavior:** In calculus and pre-calculus, understanding the behavior of functions often involves analyzing their simplified forms, especially when dealing with asymptotes or removable discontinuities (holes). \* **Foundation for Advanced Math:** Simplifying rational expressions is a foundational skill that underpins many more advanced mathematical concepts. Mastering it builds a solid base for future learning.

## The Core Principles of Simplifying Rational Expressions

The fundamental principle behind simplifying any fraction, including rational expressions, is to **cancel out common factors**. Think of it like this: if you have  $\frac{3 \times 5}{3 \times 7}$ , you can cancel the '3' from both the numerator and denominator because anything divided by itself is 1. This leaves you with  $\frac{5}{7}$ . When simplifying rational expressions, the "factors" are polynomials or terms that are multiplied together. The process generally involves: 1. **Factoring:** This is the most critical step. You need to factor both the numerator and the denominator completely. This might involve techniques like: \* Greatest Common Factor (GCF) \* Difference of Squares ( $a^2 - b^2 = (a-b)(a+b)$ ) \* Sum/Difference of Cubes \* Trinomial Factoring (quadratic expressions) \* Factoring by Grouping 2. **Identifying Common Factors:** Once factored, scan both the numerator and denominator for identical expressions or terms. 3. **Canceling Common Factors:** For every pair of identical factors found in the numerator and denominator, you can cancel them out. Remember, you're effectively dividing one by the other, resulting in 1. 4. **Writing the Simplified Expression:** The remaining terms in the numerator and denominator form your simplified rational expression.

# Step-by-Step Guide to Simplifying Rational Expressions

Let's walk through some examples to solidify these principles.

## Example 1: Simple Factoring

Simplify:  $\frac{3x + 6}{6x + 12}$  \* **Step 1: Factor the Numerator:** The greatest common factor (GCF) of  $3x$  and  $6$  is  $3$ . So,  $3x + 6 = 3(x + 2)$ . \* **Step 2: Factor the Denominator:** The GCF of  $6x$  and  $12$  is  $6$ . So,  $6x + 12 = 6(x + 2)$ . \* **Step 3: Rewrite the Expression:**  $\frac{3(x + 2)}{6(x + 2)}$  \* **Step 4: Identify and Cancel Common Factors:** We see  $(x + 2)$  in both the numerator and the denominator.  $\frac{3 \cancel{(x + 2)}}{6 \cancel{(x + 2)}}$  \* **Step 5: Simplify Remaining Terms:** We are left with  $\frac{3}{6}$ . This can be further simplified to  $\frac{1}{2}$ . Therefore, the simplified expression is  $\frac{1}{2}$ .

## Example 2: Factoring a Difference of Squares

Simplify:  $\frac{x^2 - 9}{x + 3}$  \* **Step 1: Factor the Numerator:** The numerator is a difference of squares ( $x^2 - 3^2$ ). So,  $x^2 - 9 = (x - 3)(x + 3)$ . \* **Step 2: Factor the Denominator:** The denominator is already in its simplest form,  $x + 3$ . \* **Step 3: Rewrite the Expression:**  $\frac{(x - 3)(x + 3)}{x + 3}$  \* **Step 4: Identify and Cancel Common Factors:** The common factor is  $(x + 3)$ .  $\frac{(x - 3) \cancel{(x + 3)}}{\cancel{(x + 3)}}$  \* **Step 5: Write the Simplified Expression:** The simplified expression is  $x - 3$ .

## Example 3: Factoring Trinomials

Simplify:  $\frac{x^2 + 5x + 6}{x^2 + 7x + 10}$  \* **Step 1: Factor the Numerator:** We need two numbers that multiply to 6 and add to 5. These numbers are 2 and 3. So,  $x^2 + 5x + 6 = (x + 2)(x + 3)$ . \* **Step 2: Factor the Denominator:** We need two numbers that multiply to 10 and add to 7. These numbers are 2 and 5. So,  $x^2 + 7x + 10 = (x + 2)(x + 5)$ . \* **Step 3: Rewrite the Expression:**  $\frac{(x + 2)(x + 3)}{(x + 2)(x + 5)}$  \* **Step 4: Identify and Cancel Common Factors:** The common factor is  $(x + 2)$ .  $\frac{\cancel{(x + 2)}(x + 3)}{\cancel{(x + 2)}(x + 5)}$  \* **Step 5: Write the Simplified Expression:** The simplified expression is  $\frac{x + 3}{x + 5}$ .

## Important Considerations: Restrictions on the Variable

This is a crucial aspect often overlooked when simplifying rational expressions, but it's vital for a complete understanding. When simplifying, we often cancel out terms. However, we must remember that division by zero is undefined. Therefore, any value of the variable that would have made the \*original\* denominator zero must be excluded from the domain of the simplified expression. Let's revisit Example 3:  $\frac{x^2 + 5x + 6}{x^2 + 7x + 10}$ . The original denominator is  $x^2 + 7x + 10 = (x + 2)(x + 5)$ . This denominator is zero when  $x + 2 = 0$  (so  $x = -2$ ) or when  $x + 5 = 0$  (so  $x = -5$ ). Therefore, even though the simplified expression is  $\frac{x + 3}{x + 5}$ , the original expression is undefined when  $x = -2$  or  $x = -5$ . We must state these restrictions. The simplified expression is  $\frac{x + 3}{x + 5}$ , with the restrictions  $x \neq -2$  and  $x \neq -5$ .

## Handling Opposites

Sometimes, you might encounter factors that are opposites, like  $(x - 2)$  and  $(2 - x)$ . Remember that  $(2 - x) = -1(x - 2)$ . This allows you to create a common factor. Example: Simplify  $\frac{x - 2}{2 - x}$  \* **Step 1:** Rewrite the denominator:  $2 - x = -1(x - 2)$ . \* **Step 2:** Substitute:  $\frac{x - 2}{-1(x - 2)}$  \* **Step 3:** Cancel  $(x - 2)$ :  $\frac{\cancel{(x - 2)}}{-1 \cancel{(x - 2)}} = \frac{1}{-1} = -1$ . The simplified expression is  $-1$ . The restriction is  $x \neq 2$  (because  $2 - x$  would be zero).

## Common Mistakes and How to Avoid Them

\* **Canceling Terms Instead of Factors:** A very common error is canceling parts of terms that are being added or subtracted. For example, in  $\frac{x+2}{x+3}$ , you *cannot* cancel the 'x' or the '2' and '3'. You can only cancel entire common factors. \* **Correct:**  $\frac{(x+2)(x+3)}{(x+2)(x+5)} = \frac{x+3}{x+5}$  \* **Incorrect:**  $\frac{x+2}{x+3}$  (cannot cancel 'x') \* **Forgetting to Factor Completely:** Always ensure both the numerator and denominator are factored as much as possible before attempting to cancel. Missing a common factor will lead to an incomplete simplification. \* **Ignoring Restrictions:** As discussed, not stating the restrictions on the variable can lead to an incomplete or even incorrect understanding of the original expression's domain. \* **Sign Errors:** Be extra careful with negative signs during factoring and cancellation. This is where many algebraic slips occur.

## Practice Makes Perfect: Tips for Mastering Simplification

\* **Master Your Factoring Techniques:** The better you are at factoring polynomials, the faster and more accurately you'll simplify rational expressions. Dedicate time to practicing factoring quadratics, differences of squares, and GCF. \* **Work Through Examples Systematically:** Follow the steps outlined above consistently. Write down each step, especially when you're starting out. \* **Check Your Work:** After simplifying, try plugging in a few values for the variable (that are not restricted) into both the original and simplified expressions. They should yield the same result. \* **Utilize Online Resources:** There are many excellent websites and videos that offer practice problems and step-by-step solutions for simplifying rational expressions. Khan Academy, YouTube channels, and educational math websites are invaluable. \* **Seek Help When Needed:** Don't hesitate to ask your teacher, a tutor, or a study group for help if you're stuck. Understanding these concepts early will prevent frustration later on.

| No | Question                                                                                                      | Answer                                                                                                                                                                                                                                                                       |
|----|---------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1  | What's the first crucial step to simplifying a rational expression, and why is it so important?               | The absolute first step is to factor both the numerator and the denominator completely. This is critical because it reveals common factors that can then be canceled out, leading to the simplified form.                                                                    |
| 2  | How do I know when a rational expression is fully simplified?                                                 | A rational expression is fully simplified when there are no common factors (other than 1) between the numerator and the denominator. Think of it like reducing a fraction to its lowest terms.                                                                               |
| 3  | What happens if I forget to factor out a common term? Will my answer still be considered correct?             | While you might get closer, the expression won't be fully simplified. A correctly simplified expression requires all common factors to be identified and canceled. It's like not reducing a fraction all the way.                                                            |
| 4  | Are there any special rules or considerations when simplifying rational expressions involving negative signs? | Yes! Be mindful of negative signs. You can move a negative sign from the numerator to the denominator, or out in front of the fraction, as long as the overall value remains the same. Factoring out a -1 can often help manage these.                                       |
| 5  | What are 'excluded values' in rational expressions, and how do they relate to simplification?                 | Excluded values are the numbers that would make the original denominator zero, thus making the expression undefined. These values must be stated <i>*before*</i> simplification, as canceling factors can sometimes hide these restrictions.                                 |
| 6  | When factoring, if I have something like $(x-2)$ and $(2-x)$ , how do I handle that for simplification?       | Recognize that $(2-x)$ is the opposite of $(x-2)$ . You can rewrite $(2-x)$ as $-1(x-2)$ . This allows you to cancel the $(x-2)$ terms, leaving a negative sign to be dealt with.                                                                                            |
| 7  | Can I cancel terms if they look similar but are not identical, like ' $x+2$ ' and ' $x-2$ '?                  | No, you can only cancel identical factors. ' $x+2$ ' and ' $x-2$ ' are distinct algebraic expressions and cannot be canceled with each other, even though they share ' $x$ '.                                                                                                |
| 8  | What's a common mistake students make when simplifying rational expressions, and how can I avoid it?          | A very common mistake is canceling terms that are part of an addition or subtraction. Remember, you can only cancel <i>*factors*</i> . For example, in $(x+2)/x$ , you cannot cancel the ' $x$ 's. Always ensure you're canceling entire, identical factors after factoring. |

## Simplifying Rational Expressions: Your Comprehensive Answer Key and Analytical Guide

Rational expressions, those fundamental building blocks of algebra, often present a daunting challenge for students. The journey from a complex fraction involving polynomials to its most concise form can feel like navigating a labyrinth. This is where understanding how to simplify rational expressions becomes paramount. But what truly constitutes a simplified rational expression, and how do we get there? This article serves as your detailed, analytical answer key, dissecting the process, highlighting common pitfalls, and offering strategies for mastery, all while keeping SEO best practices in mind to ensure you find the answers you're looking for.

We'll delve deep into the techniques required, from factoring polynomials to identifying and canceling common factors. Whether you're a student seeking clarity, an educator looking for supplementary resources, or a curious mind exploring the elegance of algebraic manipulation, this guide aims to demystify the concept of simplifying rational expressions. Expect to encounter terms like [rational expressions](#), [simplification](#), [factoring](#), [common factors](#), [domain restrictions](#), and advanced techniques for [complex rational expressions](#).

### What is a Rational Expression?

Before we can simplify, let's define our terms. A [rational expression](#) is essentially a fraction where the numerator and the denominator are polynomials. Think of it as the algebraic equivalent of a numerical fraction (like  $\frac{1}{2}$  or  $\frac{3}{4}$ ), but with variables and exponents involved. For example,  $\frac{x^2 - 4}{x - 2}$  is a rational expression, as are  $\frac{3x + 6}{x^2 + 5x + 6}$  and  $\frac{y^3 - 1}{y^2 + y + 1}$ .

The key characteristic is that the polynomials involved can be of any degree. This opens the door to a wide array of algebraic structures that can be simplified. Understanding the fundamental nature of these expressions is the first step towards mastering their manipulation.

### The Goal of Simplification

The primary objective when [simplifying rational expressions](#) is to reduce them to their lowest terms. This means eliminating any common factors that exist between the numerator and the denominator. Just like simplifying the numerical fraction  $\frac{6}{12}$  to  $\frac{1}{2}$  by dividing both parts by their greatest common divisor (6), we aim to do the same with polynomial expressions.

Why is this important? Simplified rational expressions are easier to analyze, evaluate, and use in further algebraic operations like addition, subtraction, multiplication, and division of rational expressions. They also reveal underlying structures and relationships that might be obscured in their unsimplified form. Furthermore, understanding simplification is foundational for topics like graphing rational functions and solving rational equations.

### Key Steps to Simplifying Rational Expressions

The process of simplifying rational expressions can be broken down into a few fundamental steps:

## Step 1: Factor the Numerator and Denominator Completely

This is arguably the most crucial step. You must be proficient in various [factoring techniques](#) to tackle this effectively. This includes:

1. **Greatest Common Factor (GCF):** Always look for a GCF first. For example, in  $\frac{2x^2 + 4x}{6x}$ , the GCF of the numerator is  $2x$ , and the GCF of the denominator is  $6x$ . Factoring this out would give  $\frac{2x(x + 2)}{6x}$ .
2. **Difference of Squares:**  $a^2 - b^2 = (a - b)(a + b)$ . An expression like  $x^2 - 9$  factors into  $(x - 3)(x + 3)$ .
3. **Sum and Difference of Cubes:**  $a^3 + b^3 = (a + b)(a^2 - ab + b^2)$  and  $a^3 - b^3 = (a - b)(a^2 + ab + b^2)$ .
4. **Trinomials:** Factoring quadratic trinomials of the form  $ax^2 + bx + c$  into  $(px + q)(rx + s)$  is a common requirement.
5. **Factoring by Grouping:** Useful for four-term polynomials.

The goal is to break down both the numerator and the denominator into their simplest multiplicative components – their irreducible factors.

## Step 2: Identify Common Factors

Once both polynomials are fully factored, carefully examine the factors in the numerator and the denominator. Look for identical expressions that appear in both. These are your [common factors](#).

For example, in  $\frac{(x - 2)(x + 3)}{x(x - 2)}$ , the common factor is  $(x - 2)$ .

## Step 3: Cancel Common Factors

This is where the simplification truly happens. For every common factor identified, you can cancel it out from both the numerator and the denominator. This is equivalent to dividing both the numerator and the denominator by that common factor.

Continuing the example from Step 2:  $\frac{\cancel{(x - 2)}(x + 3)}{x\cancel{(x - 2)}} = \frac{x + 3}{x}$ .

## Step 4: State Domain Restrictions

This is a critical, often overlooked, aspect of simplifying rational expressions. When you cancel common factors, you are implicitly assuming that those factors are not equal to zero. Therefore, it's essential to state the values of the variable(s) that would make the \*original\* denominator zero. These are your [domain restrictions](#), and they must be excluded from the domain of the simplified expression.

In the example  $\frac{x^2 - 4}{x - 2}$ , the original denominator is  $x - 2$ . Setting this to zero, we get  $x - 2 = 0$ , so  $x = 2$ . Therefore, the simplified expression  $\frac{x + 2}{1}$  (or simply  $x + 2$ ) is valid only for  $x \neq 2$ . Failing to note this restriction means the simplified expression is not truly equivalent to the original.

For  $\frac{(x - 2)(x + 3)}{x(x - 2)}$ , the original denominator is  $x(x - 2)$ . Setting this to zero, we find  $x = 0$  or  $x - 2 = 0$ , which means  $x = 0$  or  $x = 2$ . So, the simplified expression  $\frac{x + 3}{x}$  is valid for  $x \neq 0$  and  $x \neq 2$ .

## Common Pitfalls and How to Avoid Them

Even with a clear understanding of the steps, certain mistakes are common when [simplifying rational expressions](#). Recognizing these can save you valuable points on tests and homework:

## 1. Incorrect Factoring

The most frequent error stems from faulty [factoring](#). If your factors are wrong, everything that follows will be incorrect. Double-check your factoring by multiplying your factors back together. If you don't get the original polynomial, your factoring is wrong.

## 2. Canceling Terms Instead of Factors

A classic mistake is to cancel individual terms that look alike but are not factors. For example, in  $\frac{x + 2}{x + 3}$ , you *cannot* cancel the  $x$ 's to get  $\frac{2}{3}$ . The  $x$  and the 2 are terms in the numerator, and the  $x$  and the 3 are terms in the denominator. They are not factors of the entire numerator or denominator. Only entire common factors can be canceled.

## 3. Ignoring Domain Restrictions

As emphasized earlier, forgetting to state the domain restrictions is a significant oversight. The simplified expression is not equivalent to the original if these exclusions are not noted. Always refer back to the *original* denominator when determining these restrictions.

## 4. Canceling Negative Signs Incorrectly

Expressions like  $(x - 5)$  and  $(5 - x)$  are opposites. They are related by a factor of -1:  $(5 - x) = -1(x - 5)$ . Recognizing this can be crucial when simplifying. For instance, in  $\frac{x - 5}{5 - x}$ , you can rewrite the denominator as  $-1(x - 5)$  and then cancel:  $\frac{x - 5}{-1(x - 5)} = \frac{1}{-1} = -1$ . This simplification is valid for  $x \neq 5$ .

## 5. Not Factoring Completely

Sometimes, after an initial cancellation, the remaining numerator or denominator can be factored further. Always ensure you have factored both polynomials as much as possible before looking for [common factors](#).

## Examples with Answer Keys

Let's walk through a few examples to solidify the process.

### Example 1: Basic Simplification

**Simplify:**  $\frac{3x^2 - 3x}{x^2 - 1}$

**Step 1: Factor the numerator.** The GCF is  $3x$ , so  $3x^2 - 3x = 3x(x - 1)$ .

**Step 1 (cont.): Factor the denominator.** This is a difference of squares:  $x^2 - 1 = (x - 1)(x + 1)$ .

The expression becomes:  $\frac{3x(x - 1)}{(x - 1)(x + 1)}$

**Step 2 & 3: Identify and cancel common factors.** The common factor is  $(x - 1)$ .

$$\frac{3x\cancel{(x - 1)}}{\cancel{(x - 1)}(x + 1)} = \frac{3x}{x + 1}$$

**Step 4: State domain restrictions.** The original denominator is  $x^2 - 1$ . Setting it to zero:  $x^2 - 1 = 0$  implies  $(x - 1)(x + 1) = 0$ . Thus,  $x \neq 1$  and  $x \neq -1$ .

**Answer Key:**  $\frac{3x}{x + 1}$ , for  $x \neq 1$ ,  $x \neq -1$ .

## Example 2: Factoring Trinomials

**Simplify:**  $\frac{x^2 + 7x + 10}{x^2 + 3x - 5}$

**Step 1: Factor the numerator.** We need two numbers that multiply to 10 and add to 7. These are 2 and 5. So,  $x^2 + 7x + 10 = (x + 2)(x + 5)$ .

**Step 1 (cont.): Factor the denominator.** We need two numbers that multiply to -5 and add to 3. There are no such integers. This denominator is irreducible over the integers. (Note: It's crucial to recognize when a polynomial cannot be factored further.)

The expression is:  $\frac{(x + 2)(x + 5)}{x^2 + 3x - 5}$

**Step 2 & 3: Identify and cancel common factors.** There are no common factors between the numerator and the denominator.

**Step 4: State domain restrictions.** The original denominator is  $x^2 + 3x - 5$ . To find the roots, we can use the quadratic formula:  $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$ . Here,  $a=1$ ,  $b=3$ ,  $c=-5$ .

$$x = \frac{-3 \pm \sqrt{3^2 - 4(1)(-5)}}{2(1)} = \frac{-3 \pm \sqrt{9 + 20}}{2} = \frac{-3 \pm \sqrt{29}}{2}$$

Thus,  $x \neq \frac{-3 + \sqrt{29}}{2}$  and  $x \neq \frac{-3 - \sqrt{29}}{2}$ .

**Answer Key:**  $\frac{x^2 + 7x + 10}{x^2 + 3x - 5}$ , for  $x \neq \frac{-3 + \sqrt{29}}{2}$ ,  $x \neq \frac{-3 - \sqrt{29}}{2}$ . (In this case, no simplification occurred, but identifying restrictions is still important.)

## Simplifying Complex Rational Expressions

A [complex rational expression](#) is a rational expression where the numerator, the denominator, or both, are themselves rational expressions. They often involve fractions within fractions.

There are two primary methods for simplifying these:

### Method 1: Simplify the Numerator and Denominator Separately, Then Divide

Treat the entire numerator as one rational expression and simplify it. Do the same for the entire denominator. Once both are simplified, rewrite the complex expression as a division problem (numerator divided by denominator) and proceed with multiplying by the reciprocal.

### Method 2: Multiply by the Least Common Denominator (LCD) of All Small Fractions

Identify the LCD of all the "small" fractions that make up the complex rational expression. Multiply *both* the numerator and the denominator of the main fraction by this LCD. This will clear out all the "small" denominators.

**Example: Simplify:**  $\frac{\frac{1}{x} + \frac{1}{y}}{\frac{1}{x} - \frac{1}{y}}$

**Method 1:**

$$\text{Numerator: } \frac{1}{x} + \frac{1}{y} = \frac{y}{xy} + \frac{x}{xy} = \frac{y + x}{xy}$$

$$\text{Denominator: } \frac{1}{x} - \frac{1}{y} = \frac{y}{xy} - \frac{x}{xy} = \frac{y - x}{xy}$$

$$\text{Now divide: } \frac{\frac{y + x}{xy}}{\frac{y - x}{xy}} = \frac{y + x}{xy} \times \frac{xy}{y - x} = \frac{y + x}{y - x}$$

$$\frac{x}{y-x}$$

### Method 2:

The small fractions are  $\frac{1}{x}$  and  $\frac{1}{y}$ . Their LCD is  $xy$ . Multiply numerator and denominator by  $xy$ :

$$\frac{(\frac{1}{x} + \frac{1}{y}) \times xy}{(\frac{1}{x} - \frac{1}{y}) \times xy} = \frac{\frac{xy}{x} + \frac{xy}{y}}{\frac{xy}{x} - \frac{xy}{y}} = \frac{y+x}{y-x}$$

**Domain Restrictions:** The original denominator is  $\frac{1}{x} - \frac{1}{y}$ . Setting this to zero implies  $\frac{1}{x} = \frac{1}{y}$ , so  $x = y$ . Also,  $x \neq 0$  and  $y \neq 0$  for the initial fractions to be defined. Therefore,  $x \neq y$ ,  $x \neq 0$ ,  $y \neq 0$ .

**Answer Key:**  $\frac{y+x}{y-x}$ , for  $x \neq 0$ ,  $y \neq 0$ ,  $x \neq y$ .

## The Importance of Practice

Mastering the art of [simplifying rational expressions](#), including complex ones, is fundamentally about practice.
